LEARNING DIARY, < Mobile 2026-2027> MODULE

09.09.2026

I checked out course information more thoroughly. Additionally, I started the course by watching module tasklist videos. First video was mostly about basic actions in the android studio project. In second video, I learned about Intent object, which helped me refresh my memory about its use. I also ended up watching few more video to really grasp to its idea. Lastly, what I learned was listview. I searched on stack overflow to learn how to manually implement it in android studio, since I was only familiar with recycler view instead of that. Overall, videos were helpful to learn few new things and mostly refresh my memory.

14.09.2026

I started the first exercise. It was simply about getting numbers from text boxes after clicking the button, sum them and put the result to a box on the screen. It was a really simple task, and I did it fairly quick. Additionally, I initiated doing second exercise quicklauncher, which went smoothly.

One issue that I faced, was committing the changes throughout the process. I ended up trying different methods to reset to previous branch and then commit them again, but it lead to different branches so I had to merge branches into one.

15-16.09.2026

I continued working on quicklauncher exercise. I decided to add text edit instead of using fixed one in order to make it more interesting. After, I started my third exercise. I changed the exercise data by my own pics and adding additional part to products, which was stock.

In exercise I made small mistake in adapter constructor. I accidentally set adapter parameter to constructor variables. However, I noticed my mistake and fixed it. Without this fix final work wouldn't have run. The last problem I faced was resizing pics. I completely understood the resizing method, but resizing did not go as planned. I found out my pictures were already smaller than the display, thus the method did nothing to them.

19.09.2026

It took me a second to decide what I am going to do with my own project. Finally, I chose to create a ToDo task app and named it "My App". I started by adding main and sign-up activities, as well as few pictures to drawable. I learned to remove the picture background from pictures by using "remove background" option in image preview. In my opinion, it makes the layout to look better.

20.09.2026

Today I continued working on fundamental parts of apps, such as the main, sign-up and login activities, as well as User class. I created User class and static HashMap to store users as objects in it. I used user's email as key and User object as value to store users as object to the HashMap.

I learned and got reminded to how use static so that the users can be stored in one HashMap and can be accessed globally. The HashMap is used during sign-up and login to find user data by email.

21.09.2026

Today I initiated my work by creating the toDoTask and homePage activities. I used my HashMap to check, if the user's email and password exist to let the them login. I also edited their xml layout.

One thing that I learned was how to create assets in android studio. I did this by searching on Stack Overflow and watching YouTube tutorial. Additionally, I also learned how to add these assets to the toolbar, which was done simply by adding them to the toolbar in the xml files.

22.09.2026

Today, in order to visualize a welcome message on the homepage to the user, I used an Intent to send logged-in user's email to homepage. The email was used to find the user's username and set it along with message.

The main thing that I did was to create a Task class to save tasks as objects. Objects are then saved in a static arrayList, so that I access it globally. I also got reminded how to access radio button from radio group. This was used to get selected radio buttons text and put it as parameter to task object.

Lastly, I created list view detail for what will be shown on the list.

23.09.2026

Today I learned new things to add to my project. After some searching on stack overflow, I discovered how to add actions on toolbar's arrow.

One problem that I had was after adding tasks and going back to homepage, the tasks wouldn't show in the list. Again, on stack overflow, I found a solution by adding onRestart method. So, every time I leave the activity and return to it, it gets restarted and changes get applied if there are any.

Overall, I created adapter to add the saved tasks to the lists. Furthermore, made a task detail activity, where the details of tasks are shown and be able to get deleted with use of a button.

24.09.2026

I did not do much today. I made the task detail to show in task detail activity and activated button to delete the task when it is done. I also added action to back arrow button in task detail activity. Nothing new was learned today.

25.09.2026

I started today's part by creating new assets, customizing textviews and starting to change the color palette to more muted green. I found out how it is possible to customize different elements, for example corners, shapes and colors. I applied the changes that were necessary for my project. Also learned how to add those assets to editTexts. Additionally, I finished today's part by adding requirements for sign-up elements, so user has to fulfil certain requirements to sign up.

26.09.2026

I did little work today. My goal was to add error messages and code for errors to appear if user does not fulfil sign-up requirements. Other than this, nothing new was done.

27.09.2026

I started my work with editing the sign-up requirements and adding error boxes to the login activity. Also set basic requirements for adding tasks in toDoTask activity. I added an action on account icon on homepage as well as creating new activity called userAccounActivity. Other than this, I mainly modified the xml files layouts.

03-06.10.2026

My project has been looking really good. I added the finishing touches by editing the userAccounActivity xml layout and setting requirements for user information EditTexts. The textboxes are editable, and the changes get saved to the HashMap. The most important thing was making the email unique as a requirement in the sign-up activity.

I faced a problem, where users' tasks were saved to the same ArrayList, which causes other users' tasks to show up for the currently logged-in user. To make things simpler and avoid excessive code changes, I decided to clear the task's list when logging out.

As the last steps of the process, I created a video and a README file. I used one of my old project's README file as inspiration and as template for creating one for this project. I also recorded a video showing app's different actions as best as I could.
